Merge Sort example

Divide and Conquer Strategy

Using the **Divide and Conquer** technique, we divide a problem into subproblems. When the solution to each subproblem is ready, we 'combine' the results from the subproblems to solve the main problem.

Suppose we had to sort an array A . A subproblem would be to sort a sub-section of this array starting at index p and ending at index r , denoted as $A[p..r]$.

Divide

If q is the half-way point between p and r , then we can split the subarray $A[p..r]$ into two arrays $A[p..q]$ and $A[q+1, r]$.

Combine

When the conquer step reaches the base step and we get two sorted subarrays $A[p..q]$ and $A[q+1, r]$ for array $A[p..r]$, we combine the results by creating a sorted array $A[p..r]$ from two sorted subarrays $A[p..q]$ and $A[q+1, r]$.

MergeSort Algorithm

The MergeSort function repeatedly divides the array into two halves until we reach a stage where we try to perform MergeSort on a subarray of size 1 i.e. $p == r$.

After that, the merge function comes into play and combines the sorted arrays into larger arrays until the whole array is merged.

```
MergeSort(A, p, r):  
    if p > r  
        return  
    q = (p+r)/2  
    mergeSort(A, p, q)  
    mergeSort(A, q+1, r)  
    merge(A, p, q, r)
```

To sort an entire array, we need to call $\text{MergeSort}(A, 0, \text{length}(A)-1)$.

As shown in the image below, the merge sort algorithm recursively divides the array into halves until we reach the base case of array with 1 element. After that, the merge function picks up the sorted sub-arrays and merges them to gradually sort the entire array.

Merge sort in action

The merge Step of Merge Sort

Every recursive algorithm is dependent on a base case and the ability to combine the results from base cases. Merge sort is no different. The most important part of the merge sort algorithm is, you guessed it, `merge` step.

The merge step is the solution to the simple problem of merging two sorted lists(arrays) to build one large sorted list(array).

ADVERTISEMENTS

Compare current elements of both arrays

Copy smaller element into sorted array

Move pointer of element containing smaller element

Yes:

Copy all remaining elements of non-empty array

subarray - 1

subarray - 2

sorted combined array

Since there are no more elements remaining in the second array, and we know that both the arrays were sorted when we started, we can copy the remaining elements from the first array directly.

Merge step

Writing the Code for Merge Algorithm

subarray (we can calculate the first index of the second subarray) and the last index of the second subarray.

Our task is to merge two subarrays $A[p..q]$ and $A[q+1..r]$ to create a sorted array $A[p..r]$. So the inputs to the function are A , p , q and r

The merge function works as follows:

1. Create copies of the subarrays $L \leftarrow A[p..q]$ and $M \leftarrow A[q+1..r]$.
2. Create three pointers i , j and k
 - a. i maintains current index of L , starting at 1
 - b. j maintains current index of M , starting at 1
 - c. k maintains the current index of $A[p..q]$, starting at p .
3. Until we reach the end of either L or M , pick the larger among the elements from L and M and place them in the correct position at $A[p..q]$
4. When we run out of elements in either L or M , pick up the remaining elements and put in $A[p..q]$

In code, this would look like:

Search tutorials and examples

www.domain-name.com

```
int L[n1], M[n2];

for (int i = 0; i < n1; i++)
    L[i] = arr[p + i];
for (int j = 0; j < n2; j++)
    M[j] = arr[q + 1 + j];

// Maintain current index of sub-arrays and main array
int i, j, k;
i = 0;
j = 0;
k = p;

// Until we reach either end of either L or M, pick larger among
// elements L and M and place them in the correct position at A[p..r]
while (i < n1 && j < n2) {
    if (L[i] <= M[j]) {
        arr[k] = L[i];
        i++;
    } else {
        arr[k] = M[j];
        j++;
    }
}
```

Merge() Function Explained Step-By-Step

A lot is happening in this function, so let's take an example to see how this would work.

As usual, a picture speaks a thousand words.

Merging two consecutive subarrays of array

Step 1: Create duplicate copies of sub-arrays to be sorted

```
// Create L ← A[p..q] and M ← A[q+1..r]
int n1 = q - p + 1 = 3 - 0 + 1 = 4;
int n2 = r - q = 5 - 3 = 2;

int L[4], M[2];

for (int i = 0; i < 4; i++)
    L[i] = arr[p + i];
// L[0,1,2,3] = A[0,1,2,3] = [1,5,10,12]

for (int j = 0; j < 2; j++)
    M[j] = arr[q + 1 + j];
// M[0,1] = A[4,5] = [6,9]
```

Create copies of subarrays for merging

Step 2: Maintain current index of sub-arrays and main array

```
int i, j, k;
i = 0;
j = 0;
k = p;
```

Search tutorials and examples

www.domain-name.com

Maintain indices of copies of sub array and main array

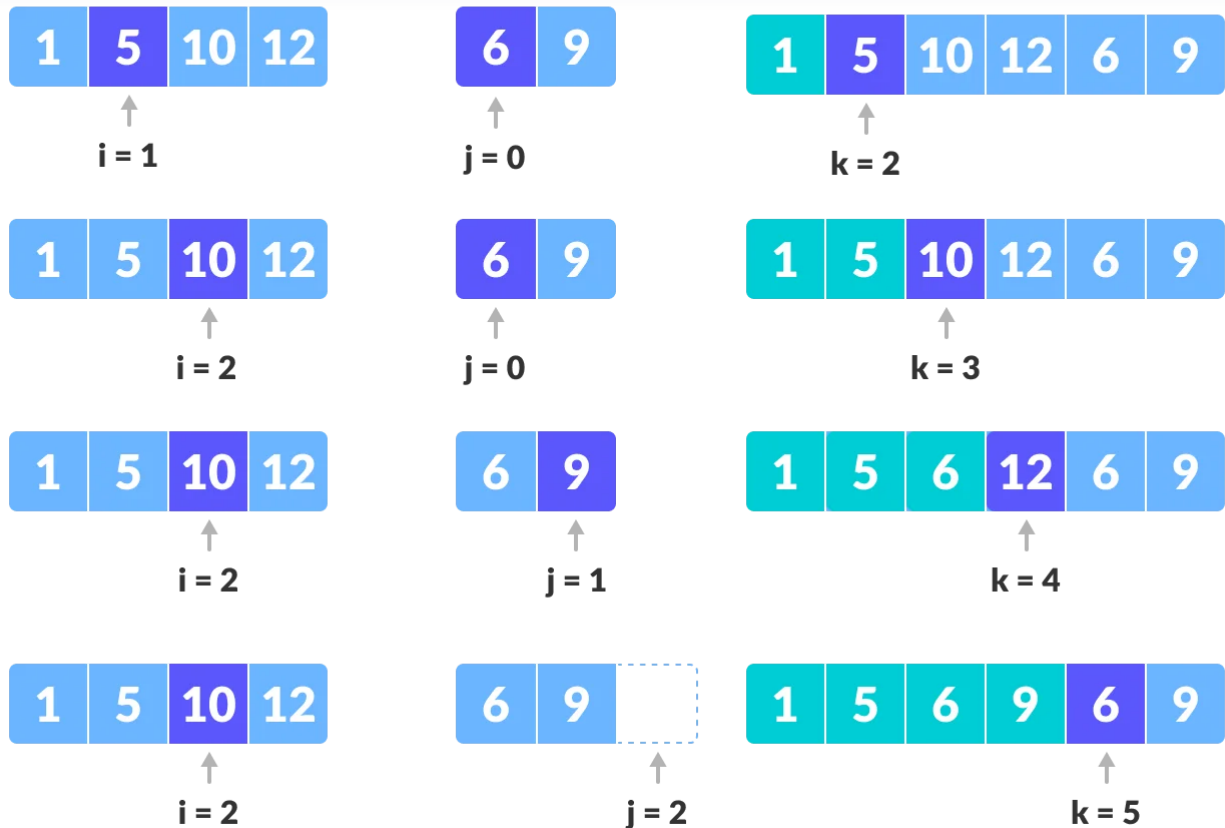

Step 3: Until we reach the end of either L or M, pick larger among elements L and M and place them in the correct position at A[p..r]

```
while (i < n1 && j < n2) {  
    if (L[i] <= M[j]) {  
        arr[k] = L[i]; i++;  
    }  
    else {  
        arr[k] = M[j];  
        j++;  
    }  
    k++;  
}
```

Search tutorials and examples

www.domain-name.com

Comparing individual elements of sorted subarrays until we reach end of one

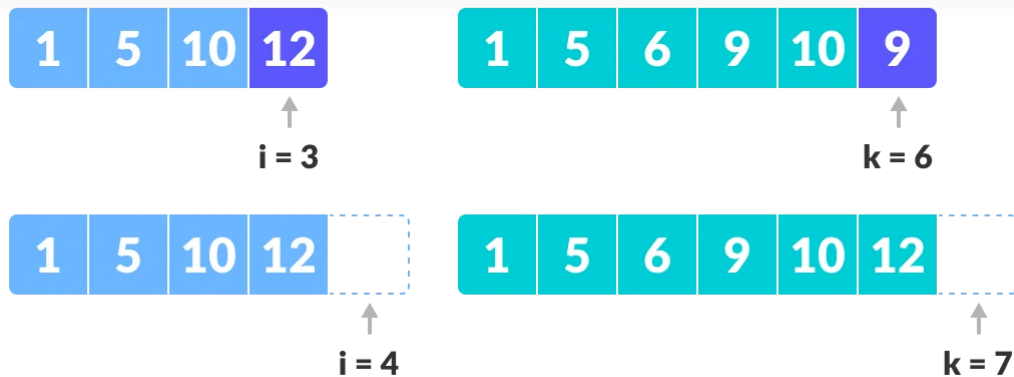

Step 4: When we run out of elements in either L or M, pick up the remaining elements and put in A[p..r]

```
// We exited the earlier loop because j < n2 doesn't hold
while (i < n1)
{
    arr[k] = L[i];
    i++;
    k++;
}
```

Search tutorials and examples

www.domain-name.com

Copy the remaining elements from the first array to main subarray

```
// We exited the earlier loop because  $i < n1$  doesn't hold
while ( $j < n2$ )
{
    arr[k] = M[j];
    j++;
    k++;
}
}
```

Copy remaining elements of second array to main subarray

This step would have been needed if the size of M was greater than L.

At the end of the merge function, the subarray $A[p..r]$ is sorted.

```
def mergeSort(array):
    if len(array) > 1:

        # r is the point where the array is divided into two subarrays
        r = len(array)//2
        L = array[:r]
        M = array[r:]

        # Sort the two halves
        mergeSort(L)
        mergeSort(M)

        i = j = k = 0

        # Until we reach either end of either L or M, pick larger among
        # elements L and M and place them in the correct position at A[p..r]
        while i < len(L) and j < len(M):
            if L[i] < M[j]:
                array[k] = L[i]
                i += 1
            else:
                array[k] = M[j]
                j += 1
            k += 1

        # When we run out of elements in either L or M,
```

Merge Sort Complexity

Time Complexity	
Best	$O(n \cdot \log n)$
Worst	$O(n \cdot \log n)$
Average	$O(n \cdot \log n)$
Space Complexity	
	$O(n)$

Search tutorials and examples

www.domain-name.com

Time Complexity

Best Case Complexity: $O(n \log n)$

Worst Case Complexity: $O(n \log n)$

Average Case Complexity: $O(n \log n)$

Space Complexity

The space complexity of merge sort is $O(n)$.
